Background and Purpose

- Stroke and traumatic brain injury (TBI) affect over 1 million Americans annually.
- Challenges related to accurate prognoses post-stroke or -TBI are a focus of much research.
- This project aimed to determine whether age at time of insult could predict improvement of functional outcomes during stay at an inpatient rehabilitation facility (IRF).

Methods

- Twenty subjects were included in the analysis (Table 1):
  - Stroke n=16 (7 female)
  - TBI n=4 (0 female)
  - Mean age 66.5 years (range: 27-82 years)
- Functional Independence Measure (FIM) scores were recorded near admission and discharge from the IRF to assess motor and cognitive function (higher scores indicate greater function).

Table 1. Subject Characteristics and Scores on Functional Measures (N=20)

<table>
<thead>
<tr>
<th>Characteristic or Measure</th>
<th>Mean (SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>66.5 (18.0)</td>
</tr>
<tr>
<td>Days since stroke/TBI</td>
<td>20.4 (8.6)</td>
</tr>
<tr>
<td>Length of stay (days)</td>
<td>9.1 (4.4)</td>
</tr>
<tr>
<td>Motor FIM (max 92):</td>
<td>30.7 (13.8)</td>
</tr>
<tr>
<td>Discharge</td>
<td>58.2 (18.1)</td>
</tr>
<tr>
<td>Motor MRFS</td>
<td>0.4 (0.2)</td>
</tr>
<tr>
<td>Cognitive FIM (max 35):</td>
<td>20.6 (6.0)</td>
</tr>
<tr>
<td>Discharge</td>
<td>28.7 (5.0)</td>
</tr>
<tr>
<td>Cognitive MRFS</td>
<td>0.5 (0.3)</td>
</tr>
</tbody>
</table>

Results

- The regression model was statistically significant, in which younger patients showed greater improvements in MRFS motor function during IRF stay (Figure 1) (F=25.01, p<0.001, β=-0.76, R²=0.58).
  - There was no correlation between age and baseline motor function, as assessed by admission motor FIM (p=0.33).
  - Younger patients tended to have poorer baseline cognitive function; thus, the trend toward significance in predicting relative improvement in cognitive function may be attributed, in part, to greater opportunities for enhancement available.

Discussion

- Findings suggest that age at the time of neurologic insult can predict relative improvement in motor outcomes in a sample of patients attending an IRF.
- Our results are consistent with previous work and extend findings to patients post-acute stroke or -TBI attending an IRF.
- Though patient age was not associated with baseline motor function, younger patients tended to have poorer baseline cognitive function; thus, the trend toward significance in predicting relative improvement in cognitive function may be attributed, in part, to greater opportunities for enhancement available.
- Mechanisms that contribute to the relationship between younger age and improved relative motor recovery may be associated with greater neuroplasticity, motivation, cognitive engagement, physical activity, or other factors.
- More research with larger samples is needed to identify mechanisms associated with this relationship.

Statistics

- The Montebello Rehabilitation Factor Score (MRFS) was calculated by using admission and discharge FIM scores to assess improvement in motor and cognitive function:
  \[
  \text{MRFS} = 100 \times \frac{\text{discharge FIM} - \text{admit FIM}}{\text{max possible FIM} - \text{admit FIM}}
  \]
- Simple linear regression was used to determine whether patient age predicted improvements in cognitive or motor function, as assessed by MRFS.
- Descriptive statistics and simple linear regression were conducted using SPSS version 24.0.
